  - · Induced structure

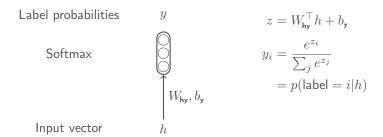

- · Repeatedly apply a non-linear transformation to sequential inputs
- · Optionally produce an output from hidden states

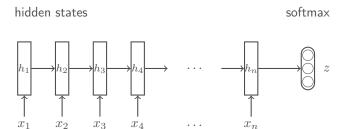

- · Repeatedly apply a non-linear transformation to sequential inputs
- · Optionally produce an output from hidden states

- · Typical output layer for multiclass classification
- . Produces scores y such that  $\sum_i y_i = 1$  nice to get probability

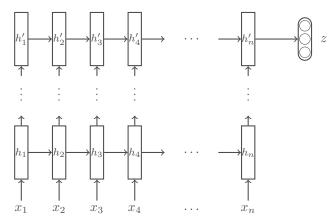

Output category label z

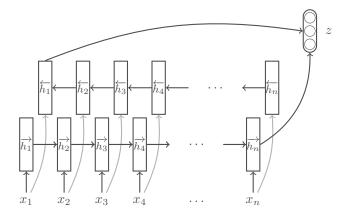

#### Deep RNN classifier

Input words  $x_1, \ldots, x_n$ 

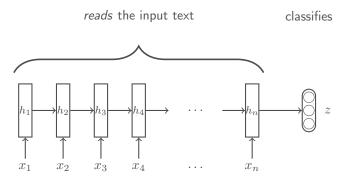

Output category label z

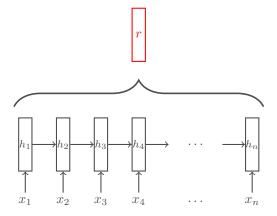

Output category label z

 ${\bf Output} \ \ {\bf category} \ \ {\bf label} \ \ z$ 

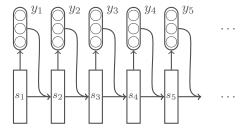

Output representation r

#### RNN language model

Input words  $y_1, \ldots, y_k$ 

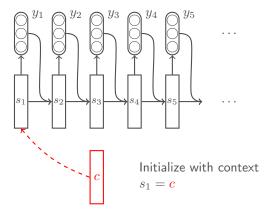

**Output** following words  $y_k, \ldots, y_m$ 

#### RNN decoder

Input context vector  $\boldsymbol{c}$ 

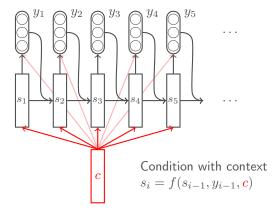

Output words  $y_1, \ldots, y_m$ 

#### RNN decoder

Input context vector c

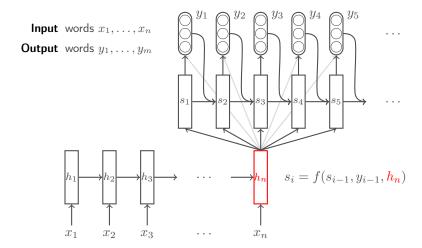

Output words  $y_1, \ldots, y_m$ 

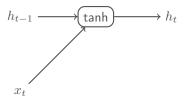

#### Sequence-to-sequence models

- · Introduced in Sutskever et al. (2014) and Cho et al. (2014)
- Combine a sequence encoder for the source language with a sequence decoder for the target language
  - 1. Encode source language tokens until <EOS> obtained
  - 2. Use final encoder hidden state as context vector
  - 3. Decode target language tokens until <EOS> obtained
- · Use gated units (LSTMs or GRUs) to overcome vanishing gradients
- Beam search decoding through softmax scores

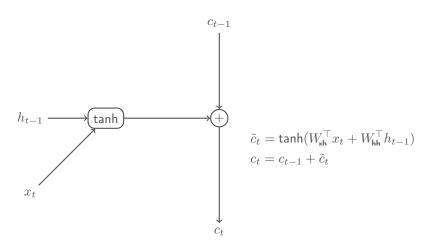

#### Sequence-to-sequence learning

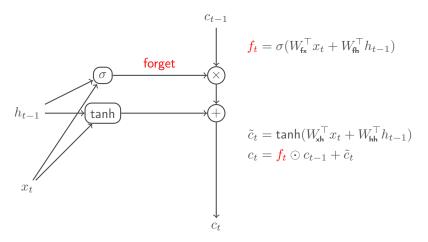

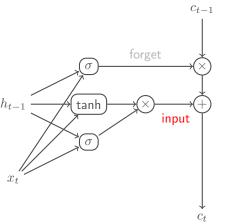

- Backpropagation through repeated non-linear transformations (sigmoid, tanh) leads to vanishing gradients
  - RNNs cannot easily model long-range dependencies
  - Performance degrades with longer sequences
- LSTM (Hochreiter & Schmidhuber, 1997) adds a memory cell which is only affected by linear interactions
- · Gates with sigmoid activations are used to modulate:
  - o additions from the current input (input gate)
  - o contributions to the next hidden state (output gate)
  - o the amount of memory decayed (forget gate) (Gers et al., 1999)

$$h_t = \tanh(W_{\mathbf{xh}}^{\top} x_t + W_{\mathbf{hh}}^{\top} h_{t-1})$$
 (normal RNN)

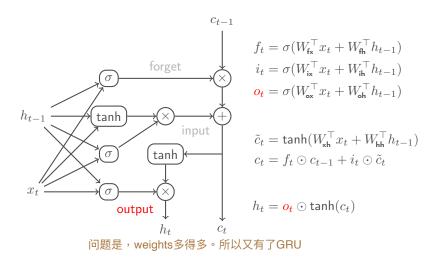

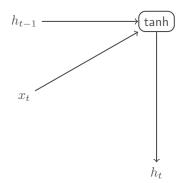

$$f_t = \sigma(W_{\mathbf{f}_{\mathbf{x}}}^{\top} x_t + W_{\mathbf{f}_{\mathbf{h}}}^{\top} h_{t-1})$$
$$\mathbf{i}_t = \sigma(W_{\mathbf{i}_{\mathbf{x}}}^{\top} x_t + W_{\mathbf{i}_{\mathbf{h}}}^{\top} h_{t-1})$$

$$\tilde{c}_t = \tanh(W_{\mathbf{xh}}^{\top} x_t + W_{\mathbf{hh}}^{\top} h_{t-1})$$

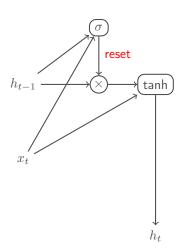

$$c_t = f_t \odot c_{t-1} + \mathbf{i_t} \odot \tilde{c}_t$$

- · Inspired by LSTM but with no memory cell (Cho et al., 2014) 只有hidden state, 没有一堆c的
- · Gates with sigmoid activations are used to control:
  - o contributions of the previous hidden state to a new state (reset gate)
  - the balance between previous and new states for the next hidden state (update gate)
- Requires fewer parameters but performs similarly to LSTM in practice (Chung et al., 2014)

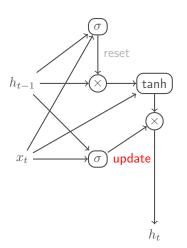

$$\begin{split} \tilde{h}_t &= \tanh(W_{\!\mathbf{x}\mathbf{h}}^\top x_t + W_{\!\mathbf{h}\mathbf{h}}^\top h_{t-1}) \\ h_t &= \tilde{h}_t \end{split}$$

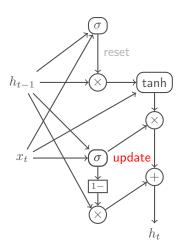

$$\mathbf{r_t} = \sigma(W_{\mathsf{rx}}^\top x_t + W_{\mathsf{rh}}^\top h_{t-1})$$

$$\begin{split} \tilde{h}_t &= \tanh(W_{\mathbf{xh}}^\top x_t + W_{\mathbf{hh}}^\top (\mathbf{r_t} \odot h_{t-1})) \\ h_t &= \tilde{h}_t \end{split}$$

$$r_t = \sigma(W_{\mathbf{rx}}^{\top} x_t + W_{\mathbf{rh}}^{\top} h_{t-1})$$
$$\mathbf{z_t} = \sigma(W_{\mathbf{zx}}^{\top} x_t + W_{\mathbf{zh}}^{\top} h_{t-1})$$

$$\begin{split} \tilde{h}_t &= \tanh(W_{\mathbf{x}\mathbf{h}}^\top x_t + W_{\mathbf{h}\mathbf{h}}^\top (r_t \odot h_{t-1})) \\ h_t &= \mathbf{z_t} \odot \tilde{h}_t \end{split}$$

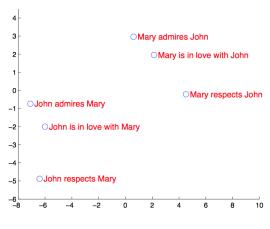

$$\begin{split} r_t &= \sigma(W_{\mathbf{rx}}^\top x_t + W_{\mathbf{rh}}^\top h_{t-1}) \\ \mathbf{z_t} &= \sigma(W_{\mathbf{zx}}^\top x_t + W_{\mathbf{zh}}^\top h_{t-1}) \end{split}$$

$$\begin{split} \tilde{h}_t &= \tanh(W_{\mathbf{x}\mathbf{h}}^\top x_t + W_{\mathbf{h}\mathbf{h}}^\top (r_t \odot h_{t-1})) \\ h_t &= (1 - z_t) \odot h_{t-1} + z_t \odot \tilde{h}_t \end{split}$$

#### Sentence embeddings

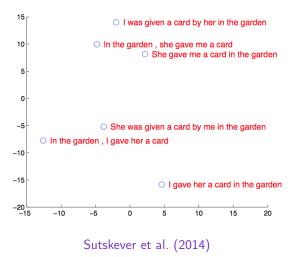

2-D PCA projections of encoded vectors for sentences

Sutskever et al. (2014)

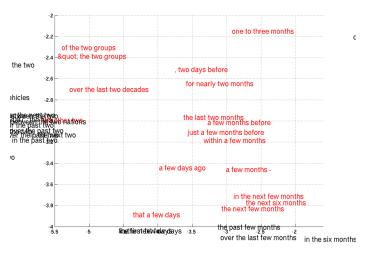

#### Sentence embeddings

#### 2-D PCA projections of encoded vectors for sentences

#### Phrase embeddings

#### 2-D Barnes-Hut projections of encoded vectors for phrases

Cho et al. (2014)

# Sequence-to-sequence models

- + First end-to-end neural architecture for machine translation
- + No alignments required, just parallel data
- + Encoders produce meaningful sentence embeddings
- Does not outperform phrase-based MT techniques
- Performance degrades for longer sentences
- Need to reverse the input for better performance

| Method                             | test BLEU score (ntst14) |
|------------------------------------|--------------------------|
| Baseline System [29]               | 33.30                    |
| Single forward LSTM, beam size 12  | 26.17                    |
| Single reversed LSTM, beam size 12 | 30.59                    |

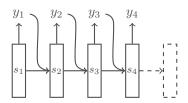

reverse: encoder是反向的。x1, x2, ..., xn->y1, 如果y1有问题,对很久之前的x1。但反向,xn, xn-1, ..., x1->y1。就比较好。 这也是为什么有些用bi-lstm,结果很好。

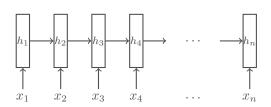

# Outline

### Attention mechanism

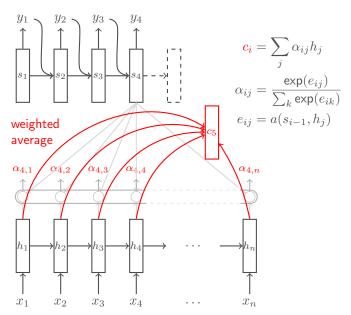

- Fixed context vector is a bottleneck for performance in encoder-decoder architectures
- Bahdanau et al. (2015) introduce a dynamic context vector that changes with each decoder timestep
  - o Weighted average over all encoder hidden states
  - Weights ("attention") conditioned on current decoder hidden state
- Allows gradients to flow directly from decoding errors to relevant encoder hidden states, thus robust to vanishing gradients

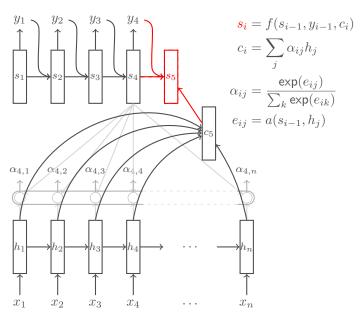

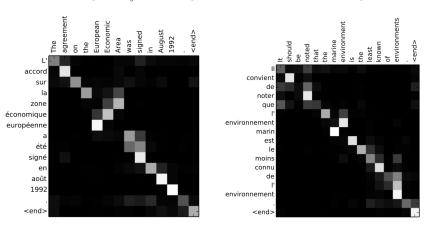

# Induced alignments

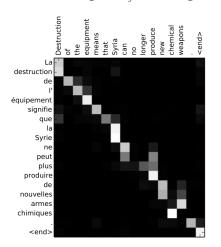

Attention weights  $\alpha_{ij}$  reveal alignments between source & target words

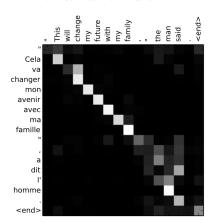

Bahdanau et al. (2015)

# Induced alignments

Attention weights  $\alpha_{ij}$  reveal alignments between source & target words

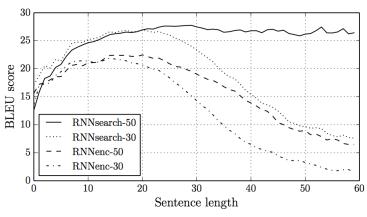

#### 注意到英语法语几乎是对角线

Bahdanau et al. (2015)

Consistent performance as sentence length increases

Bahdanau et al. (2015)

- + Gradients can be backpropagated directly to attended regions, avoiding vanishing gradients with long sequences
- + Attention weights  $\alpha_{ij}$  can be visualized to diagnose errors
- + Performance competitive with phrase-based MT

| Model         | All   | No UNK° |
|---------------|-------|---------|
| RNNencdec-30  | 13.93 | 24.19   |
| RNNsearch-30  | 21.50 | 31.44   |
| RNNencdec-50  | 17.82 | 26.71   |
| RNNsearch-50  | 26.75 | 34.16   |
| RNNsearch-50* | 28.45 | 36.15   |
| Moses         | 33.30 | 35.63   |

- Runtime for inference is  $\mathcal{O}(mn)$  instead of  $\mathcal{O}(m+n)$  without attention

- Transformers
  - · Self-attention
  - Induced structure

# Scaling up

- · Practical translation systems typically rely on phrase-based MT
  - NMT does scale easily to large vocabularies and rare words
  - Slower inference for large neural networks
  - NMT sometimes fails to fully translate all of the input
- Wu et al. (2016) describes a production-grade NMT system evaluated against phrase-based MT for Google Translate

|                                     | PBMT  | GNMT  | Human | Relative    |
|-------------------------------------|-------|-------|-------|-------------|
|                                     |       |       |       | Improvement |
| $English \rightarrow Spanish$       | 4.885 | 5.428 | 5.504 | 87%         |
| $English \to French$                | 4.932 | 5.295 | 5.496 | 64%         |
| English $\rightarrow$ Chinese       | 4.035 | 4.594 | 4.987 | 58%         |
| $Spanish \rightarrow English$       | 4.872 | 5.187 | 5.372 | 63%         |
| $French \rightarrow English$        | 5.046 | 5.343 | 5.404 | 83%         |
| $\text{Chinese} \to \text{English}$ | 3.694 | 4.263 | 4.636 | 60%         |

# Scaling up: GNMT具有bottom能这么做--可以parallel,hidden state只能是sequential

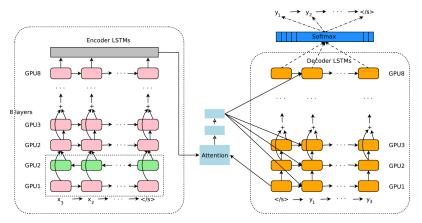

· Sequence-to-sequence model with attention (Wu et al., 2016)

Encoder: 8 LSTM layers; bottom layer bidirectional

Decoder: 8 LSTM layers; bottom layer provides attention context

efficient trick

· All layers loaded on separate GPUs

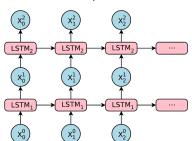

# Scaling up: Residual connections

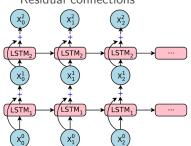

- · Stacked LSTMs with residual connections (He et al., 2015)
  - o Layer inputs added element-wise to outputs
  - o Activations model differences between layer inputs and targets
  - More robust to vanishing gradients in deep architectures

model difference instead of transformation, residual, trick from CV.

#### Normal deep LSTM

#### Residual connections

# Scaling up: Sub-word units

· Infrequent words replaced with sub-words to reduce vocabulary

- · Various corpus-based techniques to identify sub-words including
  - o WordPieceModel (Schuster & Nakajima, 2012) 日语韩语segmentation
  - o Byte Pair Encoding (Sennrich et al., 2016)
- · Available implementations:
  - o sentencepiece
  - o subword-nmt

# Scaling up: Sequence-level training

- NMT models are trained on the word level with cross-entropy loss but evaluated with sequence-level metrics like BLEU, which are non-differentiable
- · Model parameters  $\theta$  can also be refined against any non-differentiable measure R(x,y) using reinforcement learning

$$\begin{split} \nabla_{\theta} \, \mathbb{E}_{\mathcal{D}} \left[ R(x,y) \right] &= \sum_{\langle x,y \rangle \in \mathcal{D}} R(x,y) \cdot \nabla_{\theta} \, p(y|x;\theta) \\ \text{R可以是BLEU, x,y} \\ \text{分别是输入输出} &= \sum_{\langle x,y \rangle \in \mathcal{D}} R(x,y) \cdot \nabla_{\theta} \, p(y|x;\theta) \cdot \frac{p(y|x;\theta)}{p(y|x;\theta)} \\ &= \sum_{\langle x,y \rangle \in \mathcal{D}} R(x,y) \cdot \nabla_{\theta} \log p(y|x;\theta) \cdot p(y|x;\theta) \\ \text{scale gradient with BLEU} &= \mathbb{E}_{\mathcal{D}} \left[ R(x,y) \cdot \nabla_{\theta} \log p(y|x;\theta) \right] \end{split}$$

# Scaling up: Sequence-level training

- NMT models are trained on the word level with cross-entropy loss but evaluated with sequence-level metrics like BLEU, which are non-differentiable
- · Model parameters  $\theta$  can also be refined against any non-differentiable measure R(x,y) using reinforcement learning
- · GNMT: improvement in BLEU scores (but not human judgments)

| Dataset             | Trained with log-likelihood | Refined with RL |
|---------------------|-----------------------------|-----------------|
| $En \rightarrow Fr$ | 38.95                       | 39.92           |
| $En \rightarrow De$ | 24.67                       | 24.60           |

# Scaling up: Multilingual MT

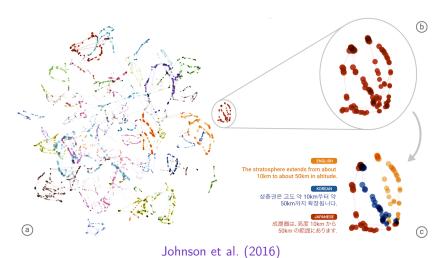

- Johnson et al. (2016) proposes a simple change to translate between multiple languages with a single NMT model
  - A token is added to the input sequence to indicate the target language for translation
  - o Vocabulary and parameters are shared across languages

#### 大部分语言都是对应于英语,所以很难有parallel data. 这样A->pivot->B

- + Can improve translation for low-resource languages with little parallel data
- + Enables zero-shot translation for language pairs with no parallel data

# Scaling up: Multilingual MT

t-SNE projections of learned representations of 74 sentences and different translations in English, Japanese and Korean

Johnson et al. (2010)

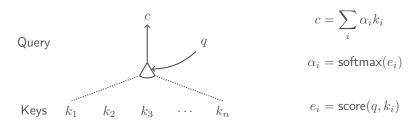

# Outline

  - Multilingual translation
- Transformers
  - · Self-attention
  - Induced structure

# Notation: Attention

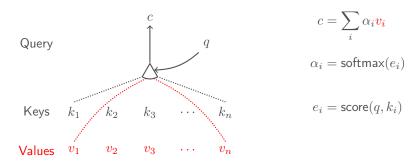

#### attention很难visualize

· Attend over keys  $k_1 \dots k_n$  conditioned on query q

### Notation: Attention

· Attend over values  $v_1 \dots v_n$  for keys  $k_1 \dots k_n$  conditioned on query q

# Scaled dot-product attention

 The original additive attention (Bahdanau et al., 2015) is a single-layer feed-forward network over a concatenated query and key.

$$\mathsf{score}(q,k) = u_{\mathbf{qk}}^{\top} \mathsf{tanh}(W_{\mathbf{qk}}^{\top}[q;k])$$

- Scaled dot-product attention (Vaswani et al., 2017) instead uses a simple dot product between the projected query and key (after a linear projection), normalized by the key dimensionality  $d_k$ 

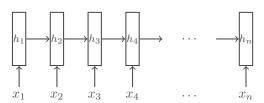

$$\mathsf{score}(q, k) = \frac{q^{\top} k}{\sqrt{d_k}}$$

where  $q = W_{\mathbf{q}}^{\top} q'$  and  $k = W_{\mathbf{k}}^{\top} k'$ 

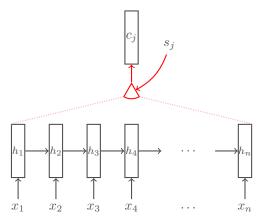

Note: values are projected separately  $v = W_{\mathbf{x}}^{\top} v'$ 

- The sequential computation of RNNs prevents parallelization for inference and also de-emphasizes long-range dependencies
- Vaswani et al., (2017) introduces a sequence model with recurrent connections replaced by self-attention
  - Hidden states for each input token are produced by attending to the all hidden states around, input sequence using the token as a query
  - Information about word positions must by injected via position
     embeddings in the input
- Recurrent layers are replaced by self-attention layers which can be stacked, each with
  - Scaled dot-product attention
  - o Multiple attention heads, projected down to the input dimensionality
  - Unseen tokens masked out (in the decoder)

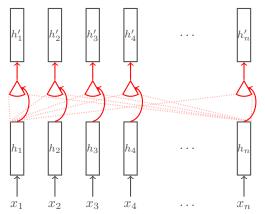

RNN encoder

#### RNN encoder with attention

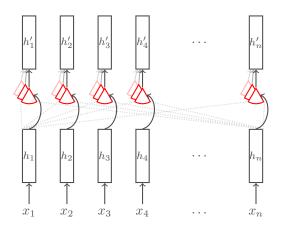

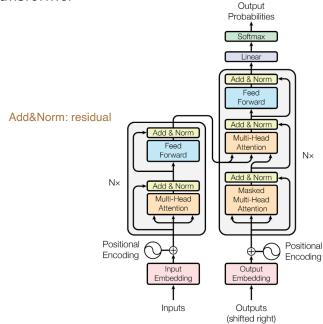

### Deep encoder with self-attention

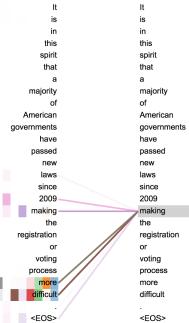

paralize, no recurrent structure.

Deep encoder with multi-head self-attention (Vaswani et al., 2017)

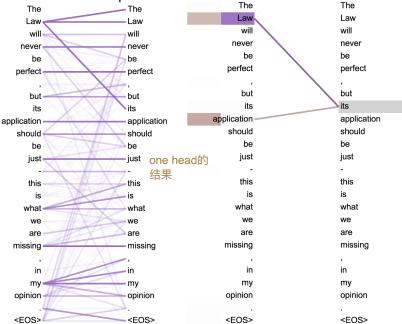

# Self-attention: Long-range dependencies

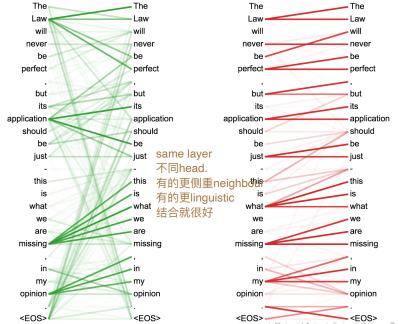

making more difficult 联系紧密,也合理 phrase

Self-attention: Anaphora resolution

## Self-attention: Clause structure

- + No recurrence, so inference can be parallelized
- + Improved runtime and performance on translation + other tasks
- + Scaled dot-product attention is efficient
- + Self-attention layers appear to capture some linguistic structure
- $-\mathcal{O}(n^2)$  comparisons for each layer (unless restricted)
- Positional embeddings are necessary to account for ordering of input
